# ANGUS II Scenario Description

## Simon Hilpert and Clemens Wingenbach

January, 2020

# Background

The ANGUS scenarios and their assumptions have been developed to model a pathway towards 100% renewable energy system in Germany. The assessed system aims to adhere with the COP Paris agreement, i.e. providing a CO2-neutral energy supply in Germany by 2050. The developed scenarios are based on the TYNDP2018, the NEP2019, the e-Highway 100%-RES scenario and the UBA RESCUE scenarios. Their main purpose is to generate storage operation profiles (power, energy) to assess underground storage technologies with regard to techno-economic indicators. Therefore, the shadow prices of the developed techno-economic energy system model play an important role as an economic signal for the storage dispatch and the model coupling (see ANGUS Case Studies). Hence, high priority is given to sensitivities that have a major effect on the storage dispatch and requirements of the future German energy system.

### **Existing Scenarios**

The scientific foundation for the ANGUS scenarios is provided by an alignment wit prominent scenarios from literature. For the mid-term perspective, the *Netzentwicklungsplan (NEP)* in combination with the Ten Year Netwok Development Plan (TYNDP) are considered. In addition, the e-Highway2050 scenarios are used as a starting point for the long-term (2050) system.

The NEP is developed by the German transmission system operator (TSOs) to plan the transmission grid in Germany. It is based on a broad public consultation phase to enable high acceptance of planned grid expansion. Similarly, TYNDP is developed by the European TSOs with regard to the European grid. The processes of the national NEP and the TYNDP are coordinated to ensure coherent national and international planning. Both of these scenarios are updated every two years. Hence, the projects reflect current and expected socio-economic developments as well as recent relevant policy decisions. Due to the public consultation and their prominent nature, these scenarios constitute import visions for the future European energy system. Another important project in the Eurpean context are the EUCO scenarios. Their data has been used as input data for the TNYDP2018. Thus, in the ANGUS project the focus will be given to the TNYDP2018 scenarios for modelling the electrical neighbouring countries of Germany in the mid-term future.

The NEP as well as the TYNDP are focussing on the short to mid-term perspective. Hence, within the ANGUS project another prominent scenario development project, the e-Highway2050 project, is used as a foundation for the scenario frame. The project has been funded by the European Commission and aimed to develop a plan for the European transmission network from 2020 to 2050. One important part of this study is the support of EU's overall policy objectives with regard to energy. The study builds upon the TYNDP2016 and includes scenarios for 100% renewable energy supply in 2050.

The scenarios projects have been chose as the major guideline for the ANGUS project. However other additional national scenarios are considered with respect to the scenario development. These include the BMWI Langfristszenarien for Germany developed by the Fraunhofer ISI and the UBA RESUCE [@katja\_purr\_wege\_2019] scenarios.

#### System with high shares of RE

In literature different scenarios for up to 100% renewable energy systems can found. Figure 1 shows installed capacities of renewable energies in Germany for systems with high share of renewables. One important factor for the required capacity / energy is the future electricity demand including the electrification of heat and transport sectors. In addition, capacity factors and biomass potentials are crucial aspects. While PV capacity factors lie within a small range of values, onshore and offshore capacity factors can vary strongly with major impacts on results. While in the BMWI Reference scenario onshore wind fullloadhours (flh) are 3527 (capacity factor of 0.403), the onshore wind production in e-Highway 100% RES scenario is modelled with 2102 flh (average capacitiy factor of 0.24). However, the avaible biomass potential can be considered to be even more imporant, as it constitutes the only dispatchable renewable energy source. The role of biomass for 100% long-term scenarios has been discussed for example by [@szarka\_interpreting\_2017].

Figure 1: Installed renewable capacities in scenarios from literature.

The lowest capacities are found in the BMWI Reference scenario. However, capacity factors for wind in the scenario are significantly higher compared to the other scenarios. In addition, this scenario only comes with a share of approx. 82% RE. The highest capacities of wind and pv are obtained in the RESCUE GL scenario. Here the 100% RE, no import and the higher demand of 796 TWh are the driving factors. Within the set of scenarios, the wind and pv capacities of e-Highway scenario are rather located at the lower end of the range. The main reason is the high biomass potential, increasing hydro capacities (in particular in Norway) and higher offshore wind capacities. This results in significant imports in Germany, but also lower in installed capacities of onshore wind and pv. In addition to

the before mentioned factors, system flexibility is another important determinate. Here grid infrastructure (spatial flexibility) and storages (temporal flexibility) have to be considered.

## Mathematical Model

Subsequently a mathematical description of the linear programming least cost optimisation model is given. Total operational cost of the system are minimised with subject to system constraints. The equations for the mathematical model are provided for the different types of the oemof-tabular components. Subsequently, endogenous model variables are denoted with x, while exogenous parameters are denoted with c. The full set of equations for oemof-tabular components can be found in the online documentation of the software.

# Objective function

The objective function will minimise all operating costs.

$$\min: \sum_{q} \sum_{t} \overbrace{c_{g}^{marginal}\_{cost} \cdot x_{g}^{flow}(t)}^{\text{operating cost}}$$

# Energy Balances (Buses)

With the set of all Buses B all inputs  $x_{i(b),b}^{flow}$  to a bus b must equal all its outputs  $x_{b,o(b)}^{flow}$ 

$$\sum_{i} x_{i(b),b}^{flow}(t) - \sum_{o} x_{b,o(b)}^{flow}(t) = 0 \qquad \forall t \in T, \forall b \in B$$

#### Loads

For the set of all loads denoted with  $l \in L$  the load  $x_l$  at timestep t equals the exogenously defined profile value  $c_l^{profile}$  multiplied by the amount of this load  $c_l^{amount}$ 

$$x_l^{flow}(t) = c_l^{profile}(t) \cdot c_l^{amount} \qquad \forall t \in T, \forall l \in L$$

## Dispatchable Supply

For the set of all dispatchable generators  $d \in D$  the flow from the component to the connected bus is limited by the defined capacity:.

$$x_d^{flow}(t) \le c_d^{capacity} \qquad \forall t \in T, \forall d \in D$$

## Volatile Supply

In contrast to dispatchble components, for all volatile components denoted with  $v \in V$  the flow is fixed to a specific value.

$$x_v^{flow}(t) = c_v^{profile}(t) \cdot c_v^{capacity} \qquad \forall t \in T, \forall v \in V$$

The set of all volatile components includes all wind-onshore, wind-offshore, solar-pv and hydro-ror

#### **Commodities**

Commodities are modelled with an upper limit on the aggregated flow of the component:

$$\sum_{t} x^{flow} k(t) \le c_k^{amount}, \quad \forall k \in K$$

#### Conversion Processes

Biomass units are modelled with a conversion process with the following equation:

$$x_{c,to}^{flow}(t) = c_c^{efficiencty} \cdot x_{c,from}^{flow}(t), \qquad \forall c \in C, \forall t \in T$$

In combination with the commodity components, their supply can be limited.

#### Reservoirs

The reservoir is modelled as a storage with a constant inflow:

$$x_r^{level}(t) = x_r^{level}(t-1) \cdot (1 - c_r^{loss\_rate}(t)) + x_r^{profile}(t) - \frac{x_r^{flow,out}(t)}{c^{efficiency}(t)} \qquad \forall t \in T, \forall r \in R$$

$$x_r^{level}(0) = c_r^{initial\_storage\_level} \cdot c_r^{capacity}$$

The inflow is bounded by the exogenous inflow profile. Thus, if the inflow exceeds the maximum capacity of the storage, spillage is possible by setting  $x_r^{profile}(t)$  to lower values.

$$0 \leq x_r^{profile}(t) \leq c_r^{profile}(t) \qquad \forall t \in T, \qquad \forall r \in R$$

The spillage of the reservoir is therefore defined by  $c_r^{profile}(t) - x_r^{profile}(t)$ . Additional constraints apply that have been omitted but can be retrieved from the oemof documentation.

#### Storages

The mathematical representation of the storage for all storages  $s \in S$  will include the flow into the storage, out of the storage and a storage level.

Intertemporal energy balance of the storage:

$$x_s^{level}(t) = \eta^{loss\_rate} x_s^{level}(t) + \eta x_{s,in}^{flow} - \eta x_{s,out}^{flow}(t) \qquad \forall t \in T, \forall s \in S$$

Bounds of the storage level variable  $x_s^{level}(t)$ :

$$x_s^{level}(t) \leq c_s^{storage capacity} \qquad \forall t \in T, \forall s \in S$$

$$x_s^{level}(1) = x_s^{level}(t_e) = 0.5 \cdot c_s^{storage capacity} \qquad \forall t \in T, \forall s \in S$$

Of course, in addition the inflow/outflow of the storage also needs to be within the limit of the minimum and maximum power.

$$-c_s^{capacity} \leq x_s^{flow}(t) \leq c_s^{capacity} \qquad \forall t \in T, \forall s \in S$$

The loss rate for the storage can be obtained by a time constant  $loss\_rate = 1 - \exp^{-\frac{1}{24 \cdot d}}$ , where d denotes the time constant in days.

## Transmission lines

Transmission lines are modelled with a transhipment approach.

$$x_{from,n}^{flow}(t) = c_n^{loss} \cdot x_{n,to}^{flow}(t), \qquad \forall n \in N, \forall t \in T$$

# Component overview

The table shows the carrier and technologies present in the scenarios and their corresponding type (i.e. oemof tabular class) and set.

carrier	tech	type	set name	index
wind	onshore	volatile	V	v
wind	offshore	volatile	V	$\mathbf{v}$
other	res	dispatchable	D	d
hydor	ror	volatile	V	$\mathbf{v}$

# **ANGUS Scenario Assumptions**

## Spatial and temporal resolution

The scenarios model the Western European energy system with one node per country. Countries modelled are:

#### AT, BE, CH, CZ, DE, DK, FR, IT, LU, NL, NO, PL, SE.

The model simulates the system on an hourly basis for one year using a perfect foresight approach with the years 2030 and 2050. Due to the regional focus of this study the German energy system is modelled with greater detail compared to the neighbouring countries.

Implications & Limitations: Intra-country grid constraints are not reflected by the model. Hence, renewable energy curtailment and/or storage demand may be underestimated.

#### Grid

The grid for 2030 and 2040 is based on the TYNDP2018 (see Annex), while the grid for 2050 is based on the e-Highway 100% RES scenario. Figure 2 shows the installed transmission capacities of the 2050 electricity system. The transmission system is modelled with a transshipment approach assuming a loss of 0.03 on the lines.

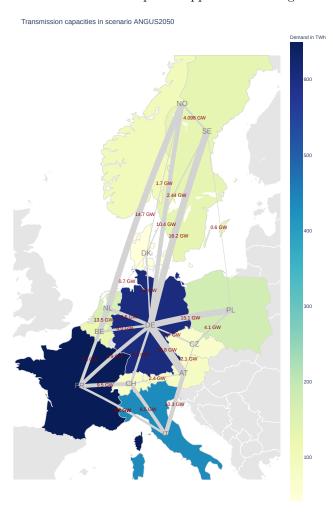

Figure 2: Installed transmission capacities in 2050.

#### Demand

### Conventional electricity demand

The German goals regarding efficiency aim to reduce the electricity demand by 10% until 2020 and 25% by 2050 compared to 2008 levels (403.8 TWh). The development of future electricity demand strongly depends on demographic and economic development as well as implemented efficiency measures. In literature, different values can be found. Assumptions regarding the electricity demand are an important driving factor for the energy system. At the same time, these values come with a high degree of uncertainty (Result of the ANGUS Scenario Workshop). While for example the conventional electricity demand within the *Reference Scenario* of the German *BMWI Langfristszenarien* accounts for 441.2 TWh in 2030 and 417.2 TWh in 2050 respectively, the demand in the NEP2019 scenarios for 2030 is slightly higher (477 TWh). Hence, depending on assumptions (demographics, efficiency and rebound effects, economic activity) the amount of conventional electricity applications can vary.

#### Sector coupling

Despite a decreasing demand due to efficiency measures, the electrification of other sectors (heat, transport) will create an additional demand for electricity. Currently the heat demand for residential heating accounts for 122.4 TWh hot water and 678.5 TWh space heating (2017). The German government set a goal of 60-80% reduction for this sector 2050. These values are very ambitious, as current values of insulation are lacking behind necessary rates. Heat demand for hot water and space heating in the RESCUE scenarios ranges from 436.8 TWh (green late scenario: GL) to 246.2 TWh (green supreme scenario: GS). These amounts correspond to a reduction of approx. 72 % to 50 % compared to 2008 (889 TWh). The supply for this heat demand is heavily based on electricity (heatpumps) with 74.6 % (GS) and 65 % (GL). The remaining energy is provided by district heating (62.4 TWh, GS) and in the case of the GL also by additional local gas boilers.

In the NEP2019 2030C scenario, additional 29 TWh electricity from heatpumps in residential heating and 25 TWh additional demand for electric vehicles are consumed. In contrast, within the BMWI scenarios, 17.8 TWh electricity for heatpumps is consumed. These values are in the range with the RESCUE green late (GL) and green supreme (GS) scenarios with 57 TWh\_th and 95 TWh\_th respectively (assuming an coefficienct of performance of approximately 3). Therefore, for 2050

both scenarios are used as a basis for additional electricity demand due to space heating.

The total electricity demand for the different scenarios is given in the Table below.

	2030NEPC	2040GCA	2050 ANGUS	$2050 \mathrm{ANGUS}$ -nb	2050ZNES
$\overline{\mathrm{AT}}$	76.55	80.5	84.82	84.82	84.82
BE	88.78	91.52	121.25	121.25	121.25
CH	58.28	57.93	77.33	77.33	77.33
CZ	70.86	76.43	71.76	71.76	71.76
DE	547	575.86	665.7	665.7	665.7
DK	46.96	53.78	42.67	42.67	42.67
FR	466.74	468.62	649.45	649.45	649.45
LU	11.05	8.26	7.38	7.38	7.38
NL	118.53	136.61	160.72	160.72	160.72
NO	149.93	148.09	102.02	102.02	102.02
PL	206.68	251.3	172.22	172.22	172.22
$\frac{SE}{}$	143.04	145.84	131.56	131.56	131.56

Demand profiles are calculated from the OPSD dataset of the ENTSOE timeseries for the selected weather year (2011).

#### Implications & Limitations:

Due to the historic demand profiles, future flexibilities like smart operation of certain applications and industry
processes are not modelled.

• The model only covers the residential hot water and space heating demand. \*Electric vehicles are modelled without specific profile for charging / discharging but only with a constant additional base load.

## Generation capacity

The different scenarios are based on the NEP2019, TYNDP2018 and the e-Highway project.

- NEP2030C: Installed capacities in Germany are based on the NEP2019 scenario 2030C. The capacities of neighbouring countries are based on the TYNDP2018-2030ST vision. The renewable share of produced energy in Germany in this scenario is approx. 68 %.
- 2040GCA: This scenario is based on the TYNDP2018-GCA vision.
- 2050ZNES: The base scenario is the e-Highway 100 % RES scenario. This scenario strongly depends on hydro capacity expansion in Norway and also substantial biomass capacity/energy. Based on the input data, this scenario has an renewable energy supply share of approx. 95 %.
- 2050ANGUS: Therefore, an adapted ANGUS scenario has been developed to model 100% renewable energy scenarios with different sensitivities such as the no-biomass (nb).

The installed capacities in Germany are shown in the Figure 3 below.

Figure 3: Installed generation capacity in Germany from 2030 to 2050 with different shares of renewables in 2050. The 2050ZNES scenario has a RE-share of 95% and 2050ANGUS scenario 100% RE-share of supply in Germany. Hydro capacities are not shown.

Note that only the scenarios 2030NEPC, 2040GCA, 2050ANGUS-(nb) depict a path towards 100% renewable energy supply.

# Renewable Energies

#### Wind and PV

Onshore wind and pv timeseries are based on renewables ninja for each country. The offshore profiles are taken from the Vernetzen-project and adapted with a correction factor of 0.8 which has been derived from the energy production in the e-Highway scenarios.

country	offshore	onshore	pv	ror
$\overline{\text{AT}}$	nan	1507	1291	3058
BE	3939	2406	1135	1335
CH	nan	1354	1416	3832
CZ	nan	1875	1226	1974

PL	3964	1834	1113	1493
SE	3792	2654	862	2161

#### Biomass potential

The maximum biomass potential per country is derived from the hotmaps project [@hotmaps\_hotmaps\_2019] and is equal for all scenarios in the ANGUS project. The potential does not cover waste but only agriculture and forestry residues. With an efficiency of 0.487 for biomass to electricity conversion the potential in Germany is approx. 73 TWh{ el}.

Biomass potential:

	Amount in TWh
$\overline{\mathrm{AT}}$	23.6111
BE	8.08333
$\mathrm{CH}$	0
CZ	32.7778

FR	149.556
LU	0.611111
NL	2.80556
NO	0
PL	71.3611
SE	86.75

# Hydro

For 2030 and 2040 hydro data has been calculated based on the TYNDP2018. The reservoir (rsv) capacity is calculated by subtracting the column *hydro-pump* from column *hydro turbine* in the original data source. Therefore, it is assumed, that each pumped hydro storage (phs) has equal pump/turbine capacities. For 2050 e-Highway database is used as a source. The storage energy capacity (max-hours) for pumped hydro is based on [@geth\_overview\_2015]. For the rsv capacity the Restore2050 data is used where storage capacities are provided in addition to the installed capacity.

The inflow in run of river and reservoirs is modelled with the inflow timeseries of the Restore2050 project. The total hydro inflow from the Restore2050 project is split by the ror-share for each scenario year. For Norway and Sweden the reservoir inflow has been scaled up to match with the e-Highway results. Similary, the run of river units for all countries except Sweden and Norway have been scaled by a factor of 1.6. The resulting fullloadhours are show in the Table below.

# Annex

# **Energy Balances**

Figure 4 shows the energy supply and demand for each scenario.

Figure 4: Energy supply and demand for all scenarios. Storage capacities have been aggregated.
